Core Solutions in Bickel Doksum: An Overview

The solutions in Bickel and Doksum are designed to elucidate complex concepts through detailed derivations, illustrative examples, and comprehensive proofs. They often address classical problems and extend them into more general or abstract settings, emphasizing asymptotic optimality and robustness. Some of the core solution themes include: - Derivation of Maximum Likelihood Estimators (MLEs) - Asymptotic distribution of estimators - Construction of confidence intervals - Optimal tests and their power properties - Nonparametric estimation procedures These solutions serve as ideal models for understanding the theoretical underpinnings of statistical inference.

Detailed Examination of Key Solutions

1. Asymptotic Normality of Estimators

One of the central solutions in Bickel and Doksum involves demonstrating the asymptotic normality of estimators, particularly the MLE. The approach typically involves: - Verifying regularity conditions (identifiability, differentiability, Fisher information positivity) - Applying Taylor expansion to the likelihood function - Utilizing the Law of Large Numbers and Central Limit Theorem (CLT) - Deriving the asymptotic distribution as a normal distribution centered at the true parameter with variance related to Fisher information Key steps in the solution: - Define the likelihood function $L(\theta)$ and the log-likelihood $\ell(\theta)$. - Show that the MLE $\hat{\theta}_n$ satisfies

the score equation $\frac{\partial \ell(\hat{\theta}_n)}{\partial \theta} = 0$. - Expand $\frac{\partial \ell(\hat{\theta}_n)}{\partial \theta}$ around the true parameter θ_0 . - Use asymptotic expansions and CLT to conclude that: $\sqrt{n}(\hat{\theta}_n - \theta_0) \xrightarrow{d} N(0, I(\theta_0)^{-1})$, where $I(\theta_0)$ is the Fisher information. Implications: This solution not only establishes the normality but also guides the construction of confidence intervals and hypothesis tests based on large-sample theory.

2. Nonparametric Estimation in the Presence of Censored Data

Another significant solution involves the estimation of distribution functions and densities when data are subject to censoring—a common scenario in survival analysis. The Kaplan-Meier Estimator: - Developed as a nonparametric maximum likelihood estimator for the survival function. - The solution involves: - Ordering observed survival times - Computing the product-limit estimator as: $\hat{S}(t) = \prod_{t_i \leq t} \left(1 - \frac{d_i}{n_i}\right)$, where d_i is the number of events at t_i , and n_i is the number at risk just prior to t_i . - Demonstrating consistency and asymptotic normality of $\hat{S}(t)$. Key aspects: - Handling censored observations via counting processes - Utilizing martingale properties for variance estimation - Deriving confidence bands for the survival function Significance: This solution framework has become standard in biostatistics, providing robust tools for analyzing time-to-event data.

3. Hypothesis Testing and Power Analysis

Bickel and Doksum also rigorously solve problems related to constructing optimal tests, such as the Neyman-Pearson lemma, and extending these to composite hypotheses. Solution highlights include: - Derivation of likelihood ratio tests (LRTs) - Use of asymptotic distribution of test statistics (chi-square, normal) - Power calculations under local alternatives - Use of Le Cam's lemmas for contiguity and asymptotic optimality Example: - Testing $H_0: \theta = \theta_0$ against $H_1: \theta \neq \theta_0$ - The LRT statistic: $\Lambda_n = 2 \left[\sup_{\theta} \ell(\theta) - \ell(\theta_0) \right]$, which asymptotically follows a chi-square distribution with degrees of freedom equal to the difference in parameter dimensions. Implication: These solutions guide the development of powerful tests with well-understood error rates, crucial for scientific inference.
