worksheet 72 rates of reaction answers serve as an essential resource for students and educators aiming to deepen their understanding of chemical kinetics. These worksheets typically include a variety of questions designed to test knowledge of the factors affecting reaction rates, the methods used to measure these rates, and the interpretation of data related to reaction kinetics. In this comprehensive guide, we will explore the key concepts covered in worksheet 72, provide detailed explanations of answers, and offer valuable tips to enhance your grasp of rates of reaction.

Understanding the Basics of Rates of Reaction

What Is the Rate of Reaction?

The rate of reaction refers to how quickly a chemical reaction occurs. It is usually expressed as the change in concentration of a reactant or product per unit time. For example, if the concentration of a reactant decreases from 0.50 mol/L to 0.30 mol/L over 10 seconds, the average rate of reaction can be calculated accordingly.

Factors Affecting Reaction Rates

Reaction rates are influenced by several key factors, including:

1. **Concentration:** Increasing the concentration of reactants generally increases the rate because more particles are available to collide.
2. **Temperature:** Higher temperatures increase reaction rates by providing particles with more kinetic energy, leading to more frequent and energetic collisions.

3. **Surface Area:** For reactions involving solids, greater surface area (e.g., powders vs. blocks) enhances the rate.
4. **Catalysts:** Catalysts provide alternative pathways with lower activation energy, speeding up reactions without being consumed.

Interpreting Worksheet 72: Common Question Types and Answers

1. Calculating Reaction Rates from Data

A typical question might provide concentration data at different time intervals and ask to calculate the average rate.

Example:

Concentration of reactant A:

Time (s): 0, 10, 20, 30

Concentration (mol/L): 0.50, 0.40, 0.30, 0.20

Calculate the average rate of the reaction between 0 and 10 seconds.

Answer: The average rate is calculated as the change in concentration over the change in time:
$$\text{Rate} = -\frac{\Delta [A]}{\Delta t} = -\frac{[A]_{\text{final}} - [A]_{\text{initial}}}{t_{\text{final}} - t_{\text{initial}}}$$
$$= -\frac{0.40\text{ mol/L} - 0.50\text{ mol/L}}{10\text{ s} - 0\text{ s}} = \frac{0.10\text{ mol/L}}{10\text{ s}} = 0.010\text{ mol/(L}\cdot\text{s)}$$
The negative sign indicates the concentration decreases, but the rate is expressed as a positive value.

2. Understanding Rate Laws and Rate Constants

Questions may ask for the formulation of the rate law based on experimental data. Example: Given the following data: - When $[A] = 0.1 \text{ mol/L}$, rate = $2.0 \text{ mol/(L}\cdot\text{s)}$ - When $[A] = 0.2 \text{ mol/L}$, rate = $8.0 \text{ mol/(L}\cdot\text{s)}$

Determine the order of the reaction with respect to A. Answer: Assuming the rate law is: $\text{Rate} = k[A]^n$ Set up ratios: $\frac{\text{Rate}_2}{\text{Rate}_1} = \left(\frac{[A]_2}{[A]_1}\right)^n$ $\frac{8.0}{2.0} = \left(\frac{0.2}{0.1}\right)^n$ $4 = 2^n$ $n = 2$ Therefore, the reaction is second order with respect to A.

3. Determining Activation Energy Using Arrhenius Equation

A common question involves calculating activation energy (E_a) from rate constants at different temperatures.

Example: Given: - $k_1 = 0.02 \text{ L/(mol}\cdot\text{s)}$ at $T_1 = 300 \text{ K}$ - $k_2 = 0.08 \text{ L/(mol}\cdot\text{s)}$ at $T_2 = 310 \text{ K}$ Calculate E_a . Answer: Use the Arrhenius equation in its linear form: $\ln\left(\frac{k_2}{k_1}\right) = \frac{E_a}{R} \left(\frac{1}{T_1} - \frac{1}{T_2}\right)$ Where $R = 8.314 \text{ J/(mol}\cdot\text{K)}$. Calculate: $\ln\left(\frac{0.08}{0.02}\right) = \ln(4) \approx 1.386$ $\frac{1}{300} - \frac{1}{310} \approx 0.003333 - 0.003226 = 0.000107 \text{ K}^{-1}$ Now, solve for E_a : $E_a = \frac{\ln(4) \times R}{0.000107} \approx \frac{1.386 \times 8.314}{0.000107} \approx \frac{11.521}{0.000107} \approx 107,795 \text{ J/mol} \approx 108 \text{ kJ/mol}$

Key Concepts from Worksheet 72 and Their Significance

Reaction Mechanisms and Rate-Determining Step

Understanding the step in a reaction mechanism that limits the overall rate is crucial. The rate-determining step (RDS) is often identified through experimental data and helps in formulating the rate law.

Integrated Rate Laws

These equations relate the concentration of reactants to time and are vital for analyzing reaction kinetics:

1. Zero-order reactions: $[A] = [A]_0 - kt$
2. First-order reactions: $\ln [A] = \ln [A]_0 - kt$
3. Second-order reactions: $\frac{1}{[A]} = \frac{1}{[A]_0} + kt$

Sample question: If a reaction follows first-order kinetics, and the concentration decreases from 0.50 mol/L to 0.25 mol/L in 20 minutes, what is the rate constant k ? Answer: Using: $\ln [A] = \ln [A]_0 - kt$ $\ln 0.25 = \ln 0.50 - k \times 20$ $-1.386 = -0.693 - 20k$ $-1.386 + 0.693 = -20k$ $-0.693 = -20k$ $k = \frac{0.693}{20} = 0.03465, \text{min}^{-1}$
