Sample CVS Pathology MCQs with Detailed Explanations

Below are representative MCQs spanning various topics, each accompanied by comprehensive explanations to deepen understanding.

1. Which of the following histological features is characteristic of atherosclerotic plaques?

A. Intimal thickening with lipid core and fibrous cap B. Medial hypertrophy with increased smooth muscle cells C. Fibrinoid necrosis of vessel walls D. Granulomatous inflammation with giant cells
Answer: A. Intimal thickening with lipid core and fibrous cap
Explanation: Atherosclerotic plaques are characterized histologically by the accumulation of lipids within the intima of arteries, forming a lipid core. This core is often covered by a fibrous cap composed of collagen and smooth muscle cells. The plaque's composition can lead to instability and rupture, precipitating thrombosis. The other options describe different vascular pathologies: medial hypertrophy (B) is typical of hypertension, fibrinoid necrosis (C) is seen in vasculitis, and granulomatous inflammation (D) is characteristic of certain vasculitides or infections.

2. The most common cause of myocardial infarction is:

A. Vasospasm of coronary arteries B. Thrombosis overlying an atherosclerotic plaque C. Embolism from the heart D. Congenital coronary anomalies
Answer: B. Thrombosis overlying an atherosclerotic plaque
Explanation: The predominant mechanism of myocardial infarction (MI) is occlusion of a coronary artery due to thrombus formation over a ruptured or eroded atherosclerotic plaque. This sudden blockage impairs blood flow, leading to ischemia and necrosis of the myocardium. Vasospasm (A) can cause transient ischemia but is less common. Embolism (C) and congenital anomalies (D) are rarer causes of MI.

3. In hypertensive heart disease, which of the following histological changes is

most characteristic?

A. Myocyte hypertrophy with interstitial fibrosis B. Loss of myocardial cells with fatty infiltration C. Granulomatous inflammation D. Amyloid deposits in the myocardium Answer: A. Myocyte hypertrophy with interstitial fibrosis Explanation: Chronic hypertension prompts the heart to adapt by hypertrophying its myocytes, especially in the left ventricle. Over time, this hypertrophy is accompanied by interstitial fibrosis, which stiffens the myocardium and impairs diastolic function. Options B, C, and D describe other cardiac pathologies: fatty infiltration (B) can occur in cardiomyopathies, granulomatous inflammation (C) in myocarditis, and amyloid deposits (D) in amyloidosis.

4. Which congenital heart defect is most commonly associated with a systolic murmur heard at the left upper sternal border?

A. Atrial septal defect B. Ventricular septal defect C. Patent ductus arteriosus D. Coarctation of the aorta Answer: B. Ventricular septal defect Explanation: Ventricular septal defect (VSD) typically produces a harsh holosystolic (pansystolic) murmur best heard at the lower left sternal border. The murmur results from blood shunting from the high-pressure left ventricle to the right ventricle during systole. Atrial septal defects (A) often produce a systolic ejection murmur at the upper left sternal border due to increased flow across the pulmonary valve. Patent ductus arteriosus (C) presents with a continuous "machinery" murmur, and coarctation (D) causes a systolic murmur heard over the back or chest but not specifically at the upper sternal border.

5. Which of the following features is most indicative of a myocardial infarction histologically?

A. Coagulative necrosis with neutrophilic infiltration B. Granulomatous inflammation C. Lipid-laden foam cells in the intima D. Amyloid deposits Answer: A. Coagulative necrosis with neutrophilic infiltration Explanation: Myocardial infarction triggers coagulative necrosis, characterized histologically by an area of dead myocardial cells with loss of nuclei and striations, surrounded initially by an infiltration of neutrophils. Over subsequent days, macrophages and granulation tissue replace necrotic tissue. Granulomatous inflammation (B) is seen in infections or vasculitis, foam cells (C) in atherosclerosis, and amyloid deposits (D) in amyloidosis.
